

Ultrasound-guided steroid injections in joints and soft tissues

Rheumatology Department Patient Information Leaflet

Welcome to The Dudley Group Rheumatology department. This leaflet will provide you with information about what to expect when you come in for ultrasound-guided injections.

Please read the leaflet and then ask the doctor who is going to do the injection any questions you may have.

What are ultrasound-guided steroid injections?

The injections are of steroid and local anaesthetic. They are given into specific areas causing pain around joints and soft tissues. Soft tissues are the tissues surrounding joints.

Ultrasound guidance may be used when an injection without guidance is technically difficult or has not provided the expected benefit.

What are the benefits?

We use local joint and soft tissue injections to try to reduce pain due to arthritis or soft tissue inflammation. The injections are useful when the pain is not adequately controlled by other measures.

How is the injection given?

The injection is carried out in the Clinical Research Unit, Russells Hall Hospital. We will ask you to lie down and will examine your joint by ultrasound. This is painless and does not involve radiation.

We will clean the area and mark it, then numb the site with some local anaesthetic or a freezing spray. The injection will be given in one of two ways:

- Using ultrasound guidance to mark the site to be injected before the injection
- or
- Using ultrasound guidance during the injection

We will discuss which method we will use for your injection during your appointment.

Is there anything that can go wrong?

There can be no guarantee that the injection will help your symptoms. Side effects after a joint or soft tissue injection are uncommon; however, all injection procedures carry some risks:

Rare complications include:

- Infection (this happens in about one in every 10,000 procedures).
- Bleeding into the joint (usually only a concern in people who have warfarin or similar blood-thinning drugs – see section on page 4).
- Allergic reactions to the local anaesthetic used in the injection.

- When a tendon or ligament area of the lower limb has been injected, there have been some reports of tendon tearing (rupture) following local steroid injections.

This is rare and most likely occurs when the pain relief from the injection encourages overuse of an already frail tendon. The ultrasound before the injection will allow some assessment of the health of the tendon, to advise whether an injection should take place.

Occasional side effects include:

- The injected area may feel sore for about 48 hours after the injection.
- Some thinning or change of colour of the skin may occur at the injection site after an injection.
- The injection may cause facial flushing.
- It may interfere with the menstrual cycle.
- People who have diabetes may find their blood sugar control is likely to deteriorate for a few weeks.

Side effects such as those seen with regular steroid treatment (e.g. weight gain, osteoporosis) are rare with local steroid injections, unless they are given frequently.

What happens after the injection?

You will rest in the Clinical Research Unit for about one hour.

You should not drive yourself home after an injection so you will need to arrange for someone to give you a lift home. If a joint/soft tissue area in the leg was injected, we will provide you with a wheel chair and, if necessary a porter, to take you back to the car.

It is a good idea to rest the affected joint(s) as much as possible for 24 to 48 hours after the injection, before gently returning to normal activity. Resting the joint(s) may help to achieve maximum benefit from the injection.

When an area next to a tendon or ligament of the lower limb has been injected, it is advised to avoid impact exercise for a period of four weeks.

You may find that your pain is worse after you have had the injection. This should subside over the next few days and you should take painkillers as normal. If the pain persists, you can call the helpline number (at the end of this information sheet), or contact your GP for advice.

In the unlikely event that you feel generally unwell after a local steroid injection, you should contact your GP immediately.

Special procedures if you are taking warfarin or similar blood-thinning medication

The risk of bleeding into a joint after a local injection if you are on **warfarin** is very small if your warfarin dose and warfarin blood tests are stable (INR less than three), and there is usually no need to discontinue warfarin before the injection.

The anticoagulation clinic will call you to attend the clinic approximately one week before your injection to check your warfarin blood test/INR and adjust your warfarin dose, if necessary. You will also be asked to attend the anticoagulation clinic on the day of your joint injection, before the injection is carried out, for a finger prick blood sample.

The result from this sample is available in seconds and will be written in your anticoagulation book (yellow book). You will be asked to take the book back to the injection clinic. If your INR is less than three, the injection will be carried out. If the INR is higher than three, the injection will be postponed and your warfarin dose will be adjusted to bring your INR down.

Occasionally, for medical reasons, your warfarin dose is adjusted to run the target INR greater than three. In this situation, your doctor will decide on the safest course of action regarding your warfarin doses and INR target around the time of the injection.

If you are on tablets such as Xarelto® (**rivaroxaban**), Eliquis® (**apixaban**), Lixiana® (**edoxaban**), Pradaxa® (**dabigatran**), or similar, for an irregular heartbeat (atrial fibrillation):

These tablets need to be stopped for a short period before your injection to minimise the risk of bleeding into the joint. Usually, we need to wait at least 24 hours after the last tablet you have taken before performing your injection, and in some cases up to three days is required. Please ask your nurse or doctor for more information.

If the doctor or nurse you saw when the decision for injection was made did not advise you about when to stop this type of medication, please ring the Rheumatology helpline (01384 244789) for advice, in good time before your appointment.

If you are on **any of these medications** due to a deep vein or lung blood clot (deep vein thrombosis or pulmonary embolism), and/or are known to have impaired kidney function, the benefits from having the injection over the risks (bleeding into the joint or further blood clots) are a lot less clear. We will need to discuss this with you.

If the blood-thinning treatment for this reason is for a limited time only, it would be safest to consider putting off the injection until your blood-thinning treatment has finished.

Please let your consultant know before the injection if any of the following apply to you:

- You are allergic to plasters, lignocaine or steroids.
- You have any other medication conditions such as diabetes or high blood pressure.
- You are pregnant.
- You are taking blood thinning medication such as warfarin.

If you have not had swabs taken to screen for carriage of MRSA since this injection was recommended to you, or if you have any other queries, please contact the Rheumatology Helpline on 01384 244789 as soon as convenient.

Can I find out more?

Arthritis Research UK can be accessed at the following weblink:

[Arthritis UK, arthritis information](#)

It has a range of information relating to methods of controlling pain in arthritis.

If you have any questions, or if there is anything you do not understand about this leaflet, please contact:

Rheumatology Helpline on 01384 244789 (9am to 5pm, Monday to Friday)

Russells Hall Hospital switchboard number: 01384 456111
